A verifying environment

as we go

(Jim Cunningham)

THIS TALK

A semi-historical overview

verification ... automated
reasoning

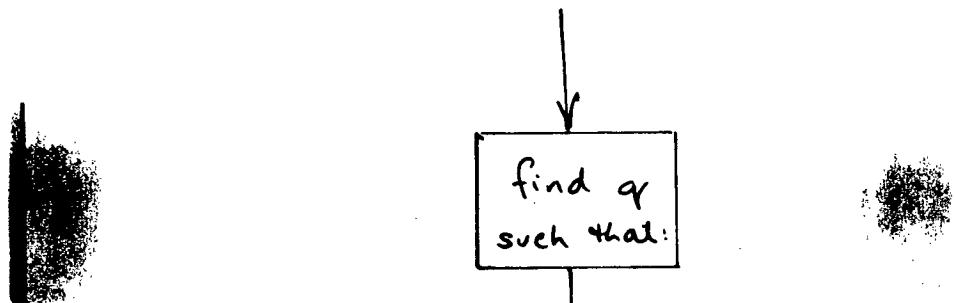

a new computing concept:

define $\ellpm =$

AVER ROOTS

Constructive Design
with Hoare-style axioms

e.g. given nats $x, y, i > 0$

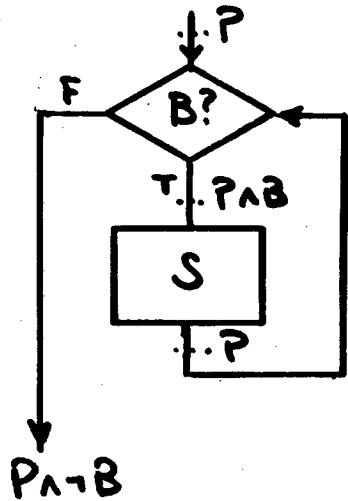

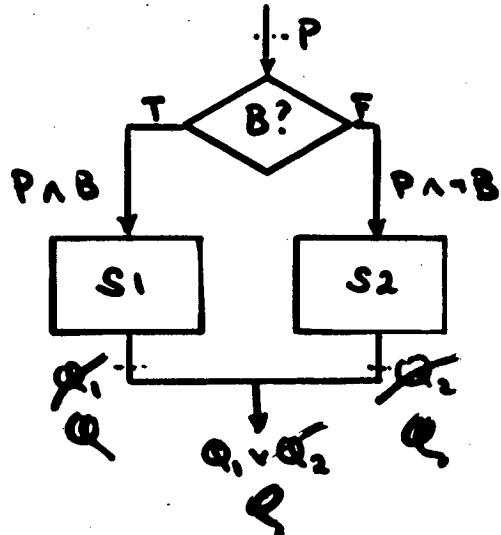

$$(x = q * y + r) \& 0 \leq r \& r < u$$

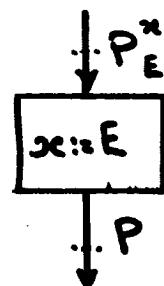

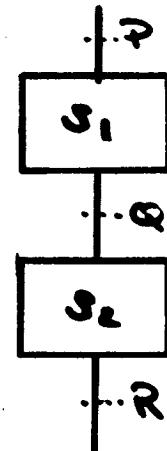

Method: fit post condition to axiom
establish precondition for axiom
force progress

VERIFICATION

(Diagrammatic)

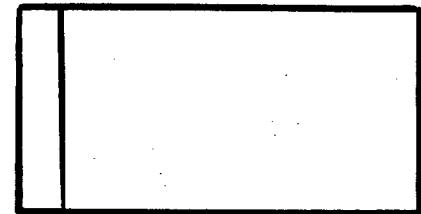

$$x := x + 1 \quad \{x+1 > 0\}$$

PROCESS SPECIFICATION

Antecedent:

input is:

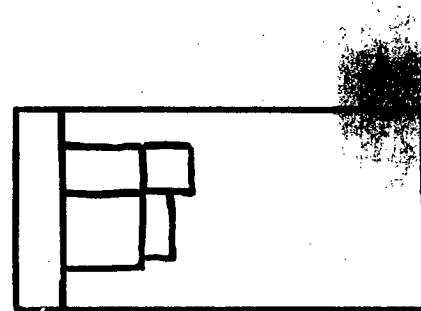

&
not all placed

Consequent

output is:

& all placed

Invariant (the difficult bit is factored out.)

if placed then on board
& without overlap
& minimising weighted distance

(now make this invariant a property of
the board data structure.)

Complementary aspect:

DATA STRUCTURE SPECIFICATION

eg: ordered set

functions

member, \leq , min

processes

put, get

A: true

C: member(x)

I: $\forall y \ y \neq x \rightarrow$
member(y)
preserved

implementations

e.g. tree + functions: root, left, right

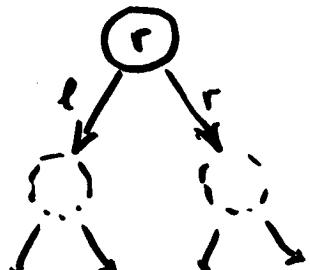

Invariant:

member(x) $\Leftrightarrow x \in \text{root}$

$\sqrt{x \in \text{root} \wedge \text{left. member}_y}$

$\vee x \text{ not } \in \text{root}$

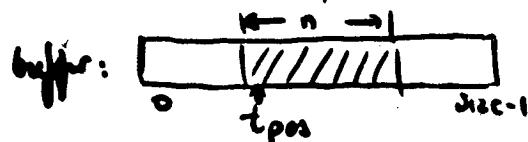

$\wedge \text{right. member}(x)$

e.g. bounded buffer

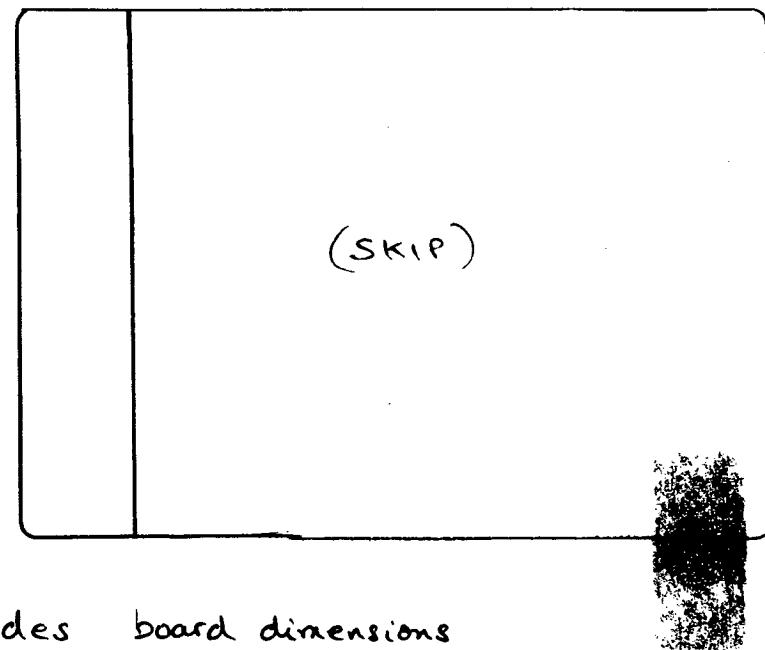

+ functions

n, size, tpos, buffer

member(x) = ?

BOARD DATA STRUCTURE

includes board dimensions

component placements

maybe connection routings

geometric expressions of invariants

assumes component data structure

type identifier

pin positions

pin types

Component dimensions

SYSTEM SPECIFICATION ?

Many processes

Many data structures

- Not a simple combination

e.g. Telephone system:

entities such as subscribers

relations which pertain

conversation (x, y)

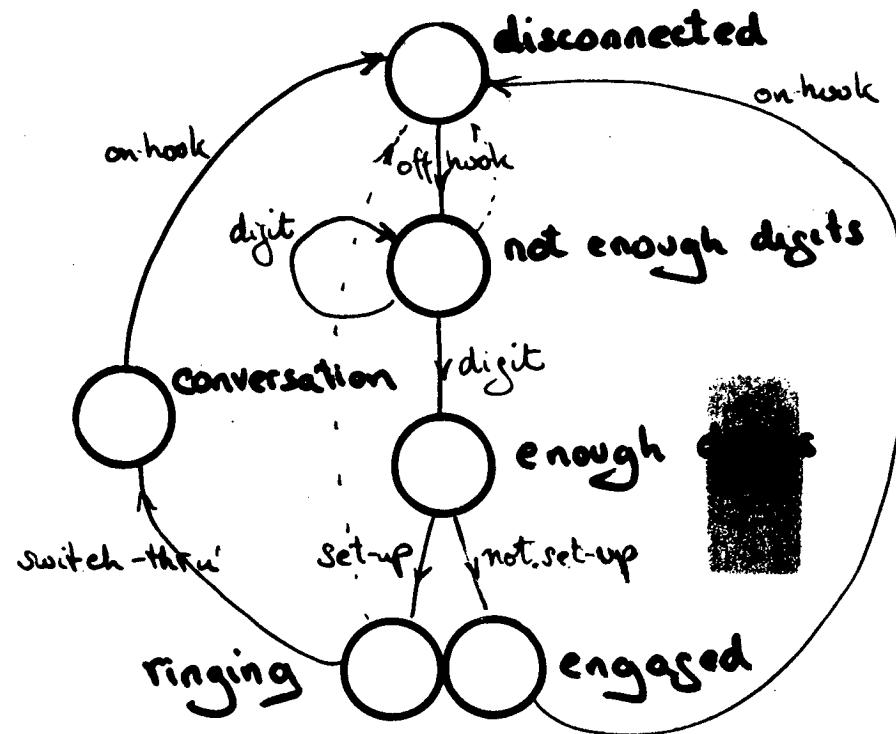

off-hook (re)

processes / actions

external dial (x, y)

internal switch-through (x, y)
clear-down (x)

Many Processes :

asynchronous behaviour
distributed implementation

partial local views

INVARIANTS FOR DISTRIBUTED SYSTEMS

Process properties difficult
for a system like an O/S
or a telephone system

But invariant properties / axioms
are easier to focus on

e.g. for a telephone system:

$\forall x, y : \text{subscriber}$,
 $(\text{conversation}(x, y) \rightarrow$
 $\text{offhook}(x) \wedge \text{offhook}(y))$

Constructive Design Steps

deny axioms (negate invariants)
find disjunctive normal forms
terms are preconditions for
processes to
restore status quo

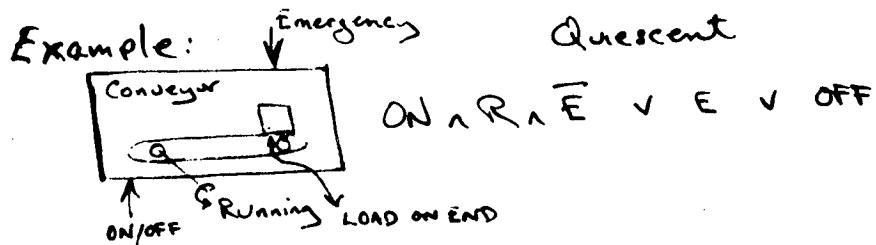

e.g. negate axiom implying
handsets off hook in conversation:

$\Rightarrow \exists x, y : \text{subscriber}$
 $\text{conversation}(x, y) \wedge \neg \text{offhook}(x)$
or $\text{conversation}(x, y) \wedge \neg \text{offhook}(y)$

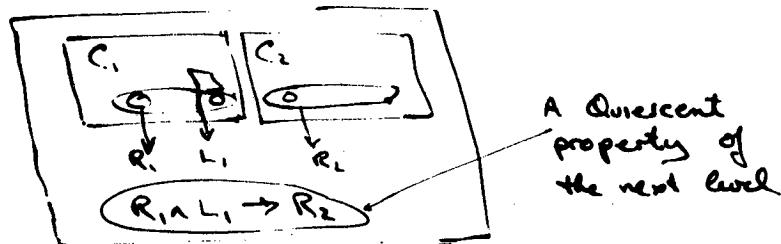

pre condition for
"clear down" process

APPLICATION : Conveyor System Example

Work by Cunningham & Kramer
on Design of Distributed Systems

HIERARCHICAL ASPECT :

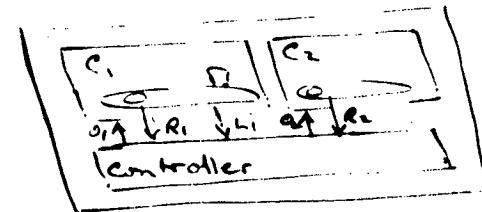

Real Example (60 pages)

Quiescents simpler than Dynamics

Covered 90% of Specified Properties

DISTRIBUTED DESIGNS

1. Quiescents of whole = Conjunction of Quiescents of parts with common variables bound

2. Invalid Quiescent \Rightarrow Precondition for action
- e.g. Suppose $L_1 \cap R_1 \rightarrow R_2$ false

$$\therefore \overline{L_1 \cap R_1} \vee R_2 \text{ false}$$

$$\therefore L_1 \cap R_1 \cap \overline{R_2} \text{ true}$$

then do something!
(one term of a disjunctive set.)

3. Hoare logic verifies the actions

i.e. {anything} before switch on C_2
ensures { R_2 } etc.

REALITY

Details rather complex

process verification still:

- guarded non-determinism
- concurrency without interference in Owicki-Gries Sense

but "natural" exploitation of first order logic proofs.

- reasoning by contradiction
- normalised forms
- even skolemisation

$\exists y \text{ conversation}(x, y)$

$\sim \text{conversation}(x, \text{dialed}(x))$

REQUIREMENTS FOR 'TOOL' SUPPORT

- 1 Mechanical Aids for any chosen logic
 - certainly for first-order logic
 - but real people use equations too
 - choice of style is important for simplicity of understanding
2. A specification database
 - with housekeeping
 - validation possibilities
 - and ways of re-using specifications
3. A hierarchical specification language
 - the formal basis was unclear, but appeared to transcend details of first order style

AVER Hierarchical Specification Language

Hierarchical abstractions

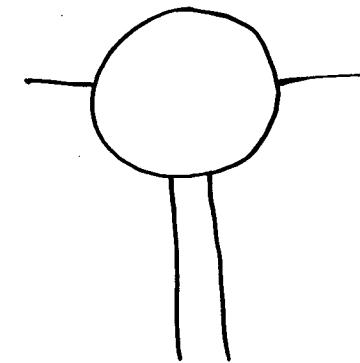

Axiomatic / Assertion

Declarative / functional

Strongly typed - see later

Composable / Modularisable

Parameterisable

define daddy = { < body,
arms,
legs > }
parameters
(normally
typed)

axioms

(body above legs) inside arms

All things to all persons

Almost without meaning

Unless you provide it by tools.

A Parameterised Structure

(loose domain interpretation
via Scott's Information Structure)

```

def lift = { (floor,
            time,
            request : time # floor # floor → bool,
            at : floor # time → bool
          )
        }

```

local definition

```

def service = { (t:time,
                 f1:floor, f2:floor
                 at
               )
               axioms
               exists t1:time,
               at(f1,t) and at(f2,t1)
               and t ≤ t1
             }

```

```

axioms all t:time,
request(t, from, to)
⇒ exists t1:time,
service(t1, from, to)
and t ≤ t1
}

```

```

def lift = temporal_logic(&)
{ (floor,
  request : floor # floor → bool,
  at : floor → bool
)
}

```

domain
combinators

AVER INTERNAL FORM

A UNIX FILE STORE

Structure of Specification

~ Structure of file store.

(Implementation by Gordon Gallacher)

MAIN FEATURES IN PRACTICE

Hierarchical domain structures are very rich and slippery, but admit many notions of inference, and considerable economy of expression.

Special logics include:

first order equational logic over hierarchically typed partial algebras

(Cunningham & Dick AP.TA '85)

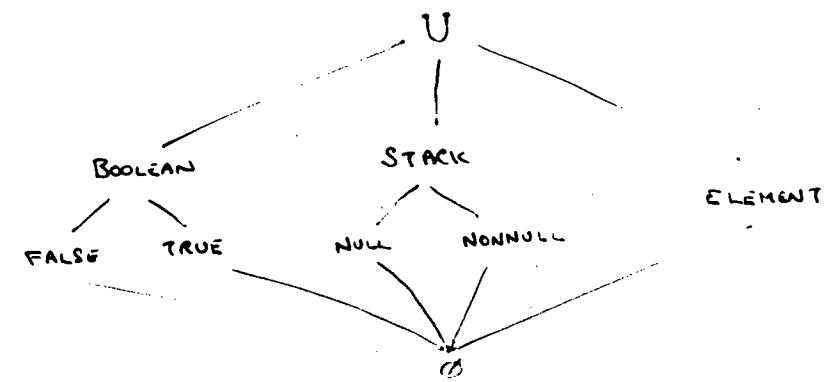

program logics built up by Dijkstra or Goldblatt axiomatiz^m
(`LNCS 130)

domain equations themselves
(Smith: Math. Sys. Th., '81)

def uft = char* ++ id \rightarrow uft !
(unbounded research)

MAIN POINTS ABOUT THE EQUATIONAL LOGIC

Simple type lattices based on subsets

Monotonic function templates

e.g., for top: $\text{NONNULL} \rightarrow \text{ELEMENT}$ implies $\text{STACK} \rightarrow \text{ELEMENT}$
for isempty: $\text{NULL} \rightarrow \text{TRUE}$ implies $\text{NULL} \rightarrow \text{BOOLEAN}$

(the templates for each function form a lattice)

Weak equality $x = x$ only if defined!

for $D_1 \cap D_2 \neq \emptyset$ $=: D_1 \times D_2 \rightarrow \text{BOOLEAN}$

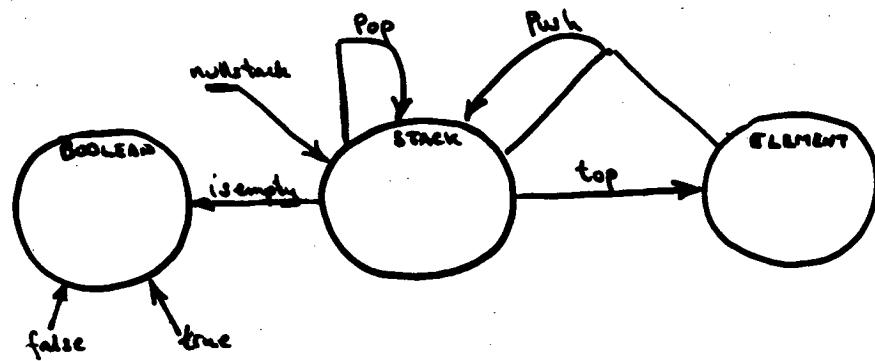

for $D_1 \cap D_2 = \emptyset$ but $D_1 \neq \emptyset$ and $D_2 \neq \emptyset$
 $=: D_1 \times D_2 \rightarrow \text{FALSE}$

for $D_1 \subseteq \emptyset$ or $D_2 \subseteq \emptyset$ $=: D_1 \times D_2 \rightarrow \emptyset$

(so equality can only hold non-empty intersections)

AVOIDING COMPLICATION & BIAS

STACK EXAMPLE

I.E. "SYNTAX"

$\text{nullstack} : \text{STACK}$
 $\text{pop} : \text{STACK} \rightarrow \text{STACK}$
 $\text{push} : \text{STACK} \times \text{ELEMENT} \rightarrow \text{STACK}$
 $\text{top} : \text{STACK} \rightarrow \text{ELEMENT}$
 $\text{isempty} : \text{STACK} \rightarrow \text{BOOLEAN}$

POSSIBLE "SEMANTICS"

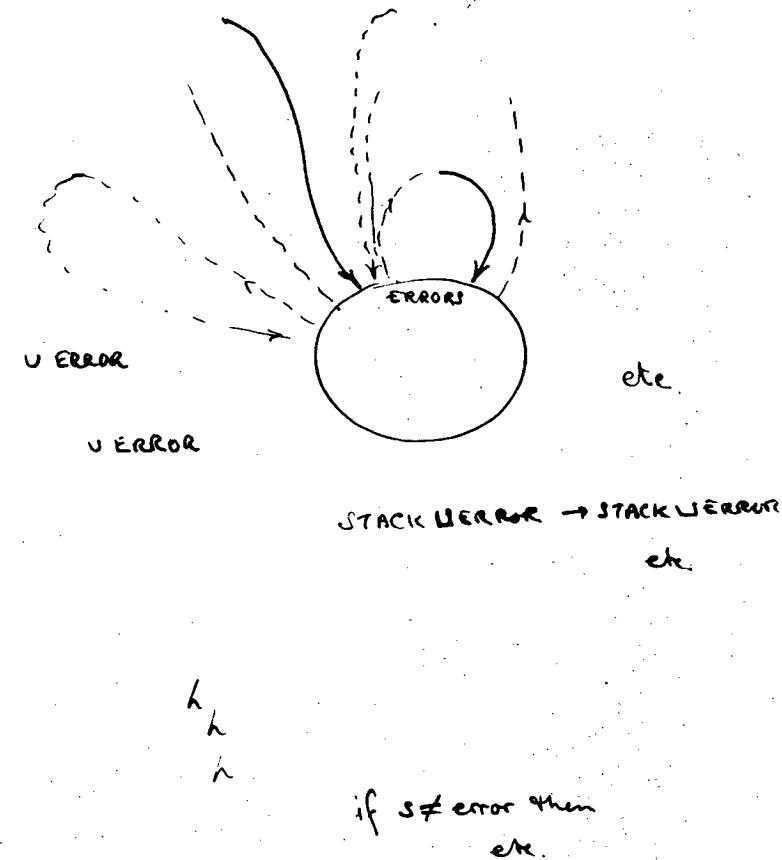

$\text{pop}(\text{push}(s, e)) = s$
 $\text{top}(\text{push}(s, e)) = e$
 $\text{isempty}(\text{nullstack}) = \text{true}$
 $\text{isempty}(\text{push}(s, e)) = \text{false}$
...

PROBLEM AREAS

$\text{top}(\text{nullstack}) = ?$
 $\text{pop}(\text{nullstack}) = \text{nullstack} ?$
 $\text{push}(\text{pop}(s), \text{top}(s)) = s ?$

\exists stack for
which
a candidate is

TOTAL ALGEBRA with ERROR TYPE

HIERARCHICAL SORTS

HIERARCHICAL / SORTED SECOND

NONNULL → STACK

NONNULL → ELEMENT

NULLSTACK → TRUE
NONNULL → FALSE

STACKERROR → STACKERROR

etc.

separate for non-error
& error domain).

top(nullstack) = ?

IMPORTANT CONSEQUENCES

1. Natural treatment of
 $\div 0$, top (nullstack),
etc. as undefined
(the original purpose)
2. More syntactic processing
in theorem proving
(& less semantic processing)
(there is a finite set of m.g.u's)
3. Conditionals can be processed
properly.

if_then_else: { bool $\times D_1 \times D_2 \rightarrow D_1 \sqcup D_2$,
true $\times D_1 \times D_2 \rightarrow D_1$,
false $\times D_1 \times D_2 \rightarrow D_2$
 $\emptyset \times D_1 \times D_2 \rightarrow \emptyset \}$

is
if (t) else
are only specifications
to use domain

Limitations of TP in Practice

"Heavy" intellectual work

Expensive on Computing Resources

Wants to cope with some perceptions
of "real" problems

e.g. flat. problems for entities

Desired strategies for few logics

FCPC

ERR

3

Strengths

Commercially valuable for
modest first problems
e.g. 20-30 var comb. logic
for valid

Inviable for theoretical. e.g.
- small abstractions of problems
& for applications in
small kernel areas
e.g. Security

OPEN

Can "real" problems
be sufficiently stratified
to give tractable TP
(at local level.) ?

How do we integrate TP
with Reasoning about Specifications
-- partial answer: specialise the TP

Remember TP explodes with poor
strategies. N.D. not good enough
for mortals.

First order Predicate logic tools
(Cunningham & Zappacosta)
SPE 1983

Basic

Parsing
 Renaming
 Closing wrt free variables
 Standardizing connector sets

Skolemize

Normalize to DNF etc
 Simplify, Factorise

Complex

Resolution Provers
 with performance issues

RESOLUTION PRINCIPLE

Two Steps

1. Classical Logic
Conjunctive Normal Form

$$(P \vee Q) \wedge (\bar{P} \vee R)$$

$$Q \vee R$$

2. Unification for Predicate Instances

$$(P(x_1) \vee Q(x_1)) \wedge (\bar{P}(a) \vee R(x_2))$$

Substitution $\sigma = \{a/x_1\}$

$$Q(a) \vee R(x_2)$$

Note

Resolution is Refutation Complete

(dual is proof complete)

\approx a proof can be expressed using resolution

Nobody promises either

i) Proof exists

or ii) TIP will find it in bounded time

So strategy is of paramount importance
(& restrictions like horn clauses only)

NET CONNECTION

Substitutions $\sigma: \text{var} \rightarrow \text{terms}$

extended to $\text{Expression} \rightarrow \text{Expression}$

Matching $M(\bar{e}, \bar{e}') = \{\sigma \mid \sigma(\bar{e}) = \bar{e}'\}$

Unification $U(E_1, E_2) = \{\sigma \mid \sigma(E_1) = \sigma(E_2)\}$

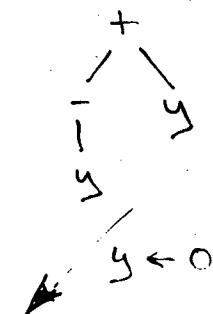

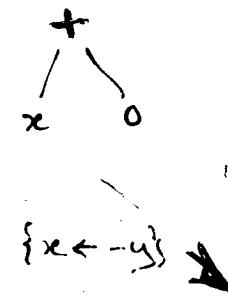

Coercion $C(E, t) = \{\sigma \mid \sigma(E) \text{ is of type } t\}$

Superposition $S(E_1, E_2) =$

$U(E_1, E_2)$ where $E_2' \stackrel{*}{\leq} E_2$

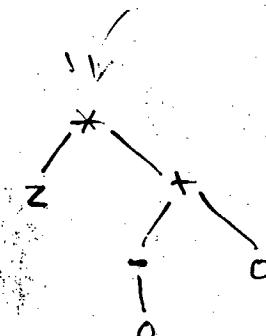

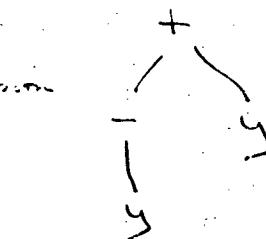

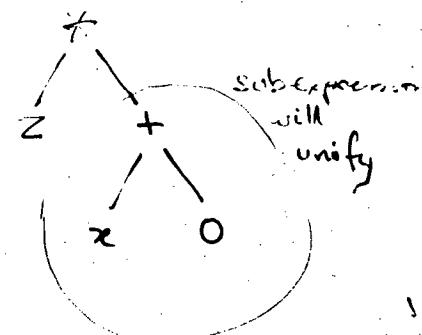

\cup $U(E_1', E_2)$ where $E_1' \stackrel{*}{\leq} E_1$

UNIFICATION

(not necessarily
a ground term)

SUPERPOSITION

CRITICAL EXPRESSION

- the key to KB & efficient ER

$$R_1: f(e, x_i) = x_i$$

$$R_2: f(x_i, e) = x_i$$

$$R_3: f(x_i, x_j) = e$$

$$R_4: f(f(x_i, x_j), x_k) = f(x_i, f(x_j, x_k))$$

Common Instance of R_3 & R_4 l.h.s found
by superposition

$$\begin{array}{ccc}
 f(f(x_1, x_1), x_2) & & \\
 \swarrow R_3 & \searrow R_4 & \\
 f(e, x_2) & & f(x_1, f(x_1, x_2)) \\
 \swarrow R_1 & & \\
 R_5: x_2 & \stackrel{=}{\text{orientation}} & \text{critical pair}
 \end{array}$$

With just two more critical pairs get: $f(x_1, x_2) = f(x_2, x_1)$

CONFLUENCE

Rewrite rules are ordered to simplify

$$\text{e.g. } f(x_1, f(x_1, x_2)) \rightarrow x_2$$

Rewrite system is finitely terminating
(no infinite loops, as with

$$x + u = u + x$$

Each expression has a normal form
so equivalence is decidable!

The Knuth-Bendix algorithm uses
critical pairs and ordering to seek
a confluent set from given axioms
but it may not exist, or
may be infinite)

STATE OF OUR ART : Conditionals & Induction

Confluent sets make equational reasoning directed and decidable

but

Superposition and critical pair generation is a powerful inference step in itself.

A Confluent Set for Stack

a: stack, b: element

$\text{pop}(\text{nullstack}) \Rightarrow \text{nullstack}$

$\text{top}(\text{push}(a, b)) \Rightarrow b$

$\text{pop}(\text{push}(a, b)) \Rightarrow a$

$\text{push}(\text{pop}(a), \text{top}(a)) \Rightarrow a$

4. Equivalence is a relation that is:

reflexive: $a \equiv a$

symmetric: $a \equiv b$ if and only if $b \equiv a$

transitive: $a \equiv c$ if $a \equiv b$ and $b \equiv c$

In a software system that is to be implemented
 S is a finite set of items some of which may be equivalent,
 E is a set of pairs of equivalent items from S ,
 EQUIV is a triadic predicate on $E \times S \times S$ such that:

$\text{EQUIV}(e, s_1, s_2)$ is true if and only if from a given set e of pairs of equivalent items it also follows
 that $s_1 \equiv s_2$

Consider the formal specification:

intuitive

INIT: $\dots \rightarrow E$
 ENTER: $E \times S \times S \rightarrow E$
 EQUIV: $E \times S \times S \rightarrow \text{Bool}$

- (1) $\text{EQUIV}(\text{INIT}, s, t) = (\text{s same as t})$
- (2) $\text{EQUIV}(\text{ENTER}(e, s, t), u, v) =$
 $\text{EQUIV}(e, u, v) \text{ or}$
 $(\text{EQUIV}(e, s, u) \text{ and } \text{EQUIV}(e, t, v))$
 $\text{or } (\text{EQUIV}(e, s, v) \text{ and } \text{EQUIV}(e, t, u))$

- a State the properties of EQUIV which should be proved in order to validate the above formal specification.

Consider also another specification in which equivalence is represented by equivalence classes, each class containing elements of E which are equivalent to each other, with a representative element selected for each class.

repclass

INIT: $\dots \rightarrow E$
 ENTER: $E \times S \times S \rightarrow E$
 REP: $E \times S \rightarrow S$

- (3) $\text{REP}(\text{INIT}, s) = s$
- (4) $\text{REP}(\text{ENTER}(e, s, t), u) =$
 $\text{if } (\text{REP}(e, t) = \text{REP}(e, u)) \text{ then } \text{REP}(e, s)$
 $\text{else } \text{REP}(e, u)$

- b Verify the representation of intuitive by repclass under the interpretation

(5) $\text{EQUIV}(e, s, t) = (\text{REP}(e, s) = \text{REP}(e, t))$

by showing that [REDACTED] are satisfied in repclass.

STATE OF THE ART : Knuth/Bendix Methods

1. Horn Clause Logic with Equality

Hsiang, ICALP '83

Paul, Eurocal '85

2. Full First Order Predicate Logic with Equality (by refutation)

(requires Associate-Commutation Unification Methods)

Coming - see Hsiang '83

3. Equation Solving by exploiting Confluence

"Narrowing"

Kirchners, Lescanne, U. of Nancy

STATE OF THE ART

Jundy / Dick 83

Equational Reasoning by "narrowing"

$$S1 \quad \log_2(x+1) + \log_2(x-1) == 3, \\ \text{ans}(x)$$

$$S2 \quad \log_2(\exp(x, 2) - 1) == 3, \text{ ans}(x)$$

$$S3 \quad \log_2(p-1) == 3, \text{ ans}(\text{n.sqrt}(p))$$

$$S4 \quad \log_2(p) == 3, \text{ ans}(\text{n.sqrt}(p+1))$$

$$S5 \quad x == 3, \text{ ans}(\text{n.sqrt}(\exp(2, x) + 1))$$

$$S6 \quad - \quad \text{ans}(\text{n.sqrt}(\exp(2, 3) + 1))$$

⋮

S10

$$\text{ans}(\text{psqrt}(\exp(2, 3) + 1))$$

20/30 rules for \log , \exp , n.sqrt etc.
these are the lemmas

STATE OF THE ART

Program Synthesis by narrowing

Axioms & Rules (>100)

for substitution

formal expressions

weakest preconditions

simple arithmetic

lists, sets etc.

No synthesis results

(but trivial verification)

Some theorems we didn't know before

REALITY

Theorem proving tools

- started earlier & better developed
- still a bit clumsy
- no panacea, but already useful

Specification system

- still very experimental
- unstable because of semantic issues
- var version new & flaky

Integration & Interface

- intermediate forms for tool/db interaction
- relation between proof structure & specification structure unclear (combinators seem to help)
- human interfaces not yet good enough for outsiders.
